Chapter 20

Enter Ascii Model

The Enter Ascii Model Package allows you to enter a model of your own and then use Bayesian probability theory to analyze that model. To use this package you do not have to have either Fortran or C installed on your server. However, If you do not have either Fortran or C installed, the only models you will be able to use are the system models. Consequently, installing both Fortran and C is strongly recommended. The interface to this package is shown in Fig. 20.1 To use this package, you must do the following:

Select the “Enter Ascii Model” package from the Package menu.

Load a Fortran or C model using the “System” or “User” buttons in the “Load And Build Model” widget group.

Load one or more Ascii data sets using the Files menu. When a data set is successfully loaded the data is plotted in the Ascii Data viewer. The format of the Ascii data that must be loaded is dependent on the model. Usually the data are two column Ascii, however, in general this package takes multicolumn Ascii data with a multicolumn abscissa. See Appendix A for a detailed description of the Ascii data files used by the Bayesian Analysis software.

Build the model using the “Build” button.

Check the Analysis Options/Find Outliers box if you suspect outliers are present in the data.

Review the prior probabilities for the loaded model using the Prior Viewer.

Select the server that is to process the analysis.

Check the status of the selected server to determine if the server is busy, change to another server if the selected server is busy.

Run the analysis on the selected server by activating the Run button.

---

1I would like to build a system library of predefined models. If you have models that you think would be of general use, I would like to hear from you. To have one of your models included, I would need the source code, the parameter file, a brief description of the model equations and data requirements.
To use the Enter Ascii package:

1. Load the Fortran or C model function from the System or User Models directory.

2. For non-system models, build the model using the “Build” button.

3. Load an ascii file having the number of abscissa specified by the model parameter file.

4. Review the prior range information, and make appropriate changes.

5. Select the server to run the analysis.

6. Run the analysis using the “Run” button.

7. Use “Get Job” to get the results from the server.

Figure 20.1: All packages that allow the user to load a Fortran or C model have the buttons titled “Load and Build Model.” These buttons allow you to load a model from either the system directory or from your user directory. They allow you to compile a model and save the current prior settings. Additionally, using the “Fortran/C Model Viewer” you can edit, modify, and create models, see Appendix E for more on creating Fortran and C models.
Get the results of the analysis by activating the Get Job button. If the analysis is running, this button will return the Accepted report containing the status of the current run. Otherwise, it will fetch and display the results from the current analysis.

20.1 The Bayesian Calculation

The calculation done by Enter Ascii Model Package is a parameter estimation calculation. However, there are two distinct functional forms for the model that are used: one using marginalization over the amplitudes, and one that does not. The model function that does not use marginalization is given by:

\[ d_j(t_i) = U_j(t_i, r_1, r_2, \ldots) + n_j(t_i) \]  

where \( d_j(t_i) \) represents a data item in the \( j \)th data set at abscissa value \( t_i \) and \( t_i \) may be vector valued. \( U_j(t_i, r_1, r_2, \ldots) \) is the model function. \( r_j \) are the various parameters appearing in the model including any amplitudes that may be present, and \( n_j(t_i) \) represents noise in the \( j \)th data set at abscissa \( t_i \). Because this model does not marginalize out the amplitudes, it is possible to restrict the amplitudes ranges using the prior probabilities.

The other model used by this package assumes the amplitudes are to be marginalized from the joint posterior probability for the parameters. The model equation that uses marginalization is similar

\[ d_j(t_i) = \sum_{\ell=1}^{m} A_{jk} G_{j\ell}(t_i, r_1, r_2, \ldots) + n_j(t_i) \]  

where the amplitudes are labeled \( A_{jk} \) meaning the \( k \)th amplitude in the \( j \)th data set, the sum is over all of the amplitudes in the model, \( G_{j\ell}(t_i, r_1, r_2, \ldots) \) is the \( \ell \)th model function in the \( j \)th data set evaluated at abscissa \( t_i \) and this model equation implicitly assumes that each data set contains the same number of amplitudes.

20.1.1 The Bayesian Calculations Using Eq. (20.1)

To compute the marginal posterior probability for each parameter using Eq. (20.1), a Markov chain Monte Carlo simulation is run targeting the joint posterior probability for all of the parameters. This joint posterior probability is represented symbolically by \( P(r_1 r_2 \ldots | DI) \). The joint posterior probability for the parameters is factored using Bayes’ theorem to obtain

\[ P(r_1 r_2 \ldots | DI) \propto P(r_1 r_2 \ldots | I)P(D | r_1 r_2 \ldots I) \]  

where \( D \) stands for all of the data in all of the data sets, \( P(r_1 r_2 \ldots \sigma_1 \ldots | I) \), is factored into independent prior probabilities for each parameter:

\[ P(r_1 r_2 \ldots | DI) \propto \prod_{j=1}^{m} P(r_j | I) \prod_{i=1}^{m} P(D | r_1 r_2 \ldots I) \]  

where \( m \) is the total number of parameters in the model. The priors, \( P(r_j | I) \), are specified in the input parameter file that describes the model. These prior are either the defaults, if you loaded the model from the system directory, or they are the priors set using the interface. Because we don’t
know the functional form of these priors, we are going to leave them in symbolic form. Factoring the direct probability for the data into an independent direct probability for each data set, one obtains

\[ P(r_1 r_2 \ldots | DI) \propto \prod_{j=1}^{m} P(r_j | I) \prod_{j=1}^{n} P(D_j | r_1 r_2 \ldots I) \]  (20.5)

as the joint posterior probability for the parameters. The direct probability for the data is a marginal likelihood, because the standard deviation of the noise prior probability is not present. Introducing a standard deviation of the noise prior probability, \( \sigma_j \), for each data set, and using the rules of probability theory to remove these parameters, one obtains:

\[ P(r_1 r_2 \ldots | DI) \propto \prod_{j=1}^{m} P(r_j | I) \prod_{j=1}^{n} \left[ \int P(\sigma_j | I) P(D_j | \sigma_j r_1 r_2 \ldots I) d\sigma_j \right]. \]  (20.6)

We have reached the point in this calculation where one has no other choice than to assign probabilities to represent each of these probabilities and then to perform the indicated integrals. Assign a Jeffreys’ prior to the prior probability for the noise standard deviation:

\[ P(\sigma_j | I) \propto \frac{1}{\sigma_j}, \]  (20.7)

and assigning the direct probability for the data using a Gaussian of standard deviation \( \sigma_j \) one obtains

\[ P(r_1 r_2 \ldots | DI) \propto \prod_{j=1}^{m} P(r_j | I) \prod_{j=1}^{n} \left[ \int Q_j(t_i, r_1, r_2, \ldots) \sigma_j^{-N_j + 1} \exp \left\{ -\frac{Q_j(t_i, r_1, r_2, \ldots)}{2\sigma_j^2} \right\} d\sigma_j \right]. \]  (20.8)

as the joint posterior probability for the parameters, where \( Q_j(t_i, r_1, r_2, \ldots) \) is given by:

\[ Q_j(t_i, r_1, r_2, \ldots) = \sum_{i=1}^{N_j} \left[ d_j(t_i) - U_j(t_i, r_1, r_2, \ldots) \right]^2, \]  (20.9)

and is the total squared residual and is essentially \( \chi^2 \). Evaluating the integral over the standard deviation of the noise, one obtains

\[ P(r_1 r_2 \ldots | DI) \propto \prod_{j=1}^{m} P(r_j | I) \prod_{j=1}^{n} \left[ \frac{Q_j(t_i, r_1, r_2, \ldots)}{2} \right]^{N_j/2} \]  (20.10)

as the joint posterior probability for the parameters, where we have dropped a number of constants that make no difference in this parameter estimation problem.

### 20.1.2 The Bayesian Calculations Using Eq. (20.2)

To compute the marginal posterior probability for each parameter using Eq. (20.2), a Markov chain Monte Carlo simulation is run targeting the joint posterior probability for all of the nonlinear parameters. In this context, nonlinear means all of the parameters appearing in the model in a
nonlinear fashion, i.e., all of the parameters except the amplitudes. This joint posterior probability is represented symbolically by \( P(r_1 r_2 \ldots | DI) \). The joint posterior probability for the nonlinear parameters is factored using Bayes’ theorem to obtain

\[
P(r_1 r_2 \ldots | DI) \propto P(r_1 r_2 \ldots | I) P(D | r_1 r_2 \ldots I)
\]

(20.11)

where \( D \) stands for all of the data in all of the data sets, the prior probability for all of the nonlinear parameters is represented by, \( P(r_1 r_2 \ldots \sigma_1 \ldots | I) \), and we will factor it into independent prior probabilities for each parameter. Consequently, the joint posterior probability for all of the nonlinear parameters is given by

\[
P(r_1 r_2 \ldots | DI) \propto \prod_{j=1}^{m} P(r_j | I) \prod_{j=1}^{n} P(D | r_1 r_2 \ldots I)
\]

(20.12)

where \( m \) is the total number of nonlinear parameters in the model. The priors, \( P(r_j | I) \), are specified in the input parameter file that describes the model. These prior are either the defaults, if you loaded the model from the system directory, or they are the priors set using the interface. Because we don’t know the functional form of these priors, we are going to leave them in symbolic form. Factoring the direct probability for the data into an independent direct probability for each data set, one obtains

\[
P(r_1 r_2 \ldots | DI) \propto \prod_{l=1}^{m} \prod_{j=1}^{n} P(D_j | r_1 r_2 \ldots I)
\]

(20.13)

as the joint posterior probability for the nonlinear parameters.

The direct probability for the data is a marginal likelihood, because neither the standard deviation of the noise prior probability nor the amplitudes are present. To proceed with this calculation, these parameters must be reintroduced into the joint posterior probability for the nonlinear parameters. Representing the standard deviation of the noise prior probability for each data set as \( \sigma_{\nu} \) and \( \{ A \}_{j} \) as all of the amplitudes in the \( j \)th data set, one obtains

\[
P(r_1 r_2 \ldots | DI) \propto \prod_{l=1}^{m} \prod_{j=1}^{n} P(D_j \sigma_{\nu} \{ A \}_{j} | r_1 r_2 \ldots I) d\sigma_{\nu} d\{ A \}_{j}
\]

(20.14)

as the joint posterior probability for the parameters. Factoring the right-hand side of this equation, one obtains

\[
P(r_1 r_2 \ldots | DI) \propto \prod_{l=1}^{m} \prod_{j=1}^{n} P(D_j \sigma_{\nu} \{ A \}_{j} | r_1 r_2 \ldots I) d\sigma_{\nu} d\{ A \}_{j}
\]

(20.15)

where \( P(D_j \sigma_{\nu} \{ A \}_{j} | r_1 r_2 \ldots I) \) is the standard deviation for the noise prior probability in the \( j \)th data set. Similarly, \( P(\{ A \}_{j} | I) \) is the joint prior probability for the amplitudes in the \( j \)th data set. If we assume the amplitudes are logically independent, then the joint prior probability for the amplitudes, \( P(\{ A \}_{j} | I) \), can be factored into a product of prior probabilities for each amplitude:

\[
P(r_1 r_2 \ldots | DI) \propto \prod_{l=1}^{m} \prod_{j=1}^{n} \prod_{k=1}^{p} P(A_{jk} | I) P(D_j \sigma_{\nu} \{ A \}_{j} | r_1 r_2 \ldots I) d\sigma_{\nu} d\{ A \}_{j}
\]

(20.16)
where \( P(A_{jk}|I) \) is the prior probability for the \( k \)th amplitude in the \( j \)th data set, and \( \nu \) is the number of data sets. We will assign a zero-mean Gaussian prior probability for each amplitude. This Gaussian prior probability is given by

\[
P(A_{jk}|I) \propto \left( \frac{2\pi \sigma_j^2}{\gamma^2 g_{jkk}} \right)^{-\frac{1}{2}} \exp \left\{ -\frac{A_{jk}^2 \gamma^2 g_{jkk}}{2\sigma_j^2} \right\} \tag{20.17}
\]

where

\[
g_{jkl} \equiv \sum_{i=1}^{N_j} G_{jk}(t_i)G_{jl}(t_i) \tag{20.18}
\]

and \( \gamma \) is used to control the width of this prior probability. The reason for this particular functional form is that it allows one to evaluate the integrals over the amplitudes in a concise functional form that aids in doing the numerical calculations. Substituting the prior probability for the amplitudes, Eq. (20.17), into the joint posterior probability for the parameters, Eq. 20.16,

\[
P(r_1 r_2 \ldots | DI) \propto \left\[ \prod_{l=1}^{m} P(r_l|I) \right\] \times \left[ \prod_{j=1}^{n} \left[ \int \frac{1}{\sigma_j} \left( \frac{2\pi \sigma_j^2}{\gamma^2 g_{j11} \cdots g_{j\nu\nu}} \right)^{-\frac{1}{2}} \exp \left\{ -\frac{\sum_{k=1}^{\nu} A_{jk}^2 \gamma^2 g_{jkk}}{2\sigma_j^2} \right\} \left[ P(D_j|\sigma_j\{ A\}_j r_1 r_2 \ldots I) d\sigma_j d\{ A\}_j \right] \right] \tag{20.19}
\]

and assigning a Gaussian for the direct probability for the data, \( P(D_j|\sigma_j\{ A\}_j r_1 r_2 \ldots I) \), one obtains:

\[
P(r_1 r_2 \ldots | DI) \propto \left\[ \prod_{l=1}^{m} P(r_l|I) \right\] \times \left[ \prod_{j=1}^{n} \left[ \int \frac{1}{\sigma_j} \left( \frac{2\pi \sigma_j^2}{\gamma^2 g_{j11} \cdots g_{j\nu\nu}} \right)^{-\frac{1}{2}} \exp \left\{ -\frac{\sum_{k=1}^{\nu} A_{jk}^2 \gamma^2 g_{jkk}}{2\sigma_j^2} \right\} \left[ (2\pi \sigma_j^2)^{-\frac{N_j}{2}} \exp \left\{ -\sum_{i=1}^{N_j} \left( \frac{d_{ji} - \sum_{k=1}^{\mu} A_{jk} G_{jk}(t_i, r_1 \cdots)}{2\sigma_j} \right)^2 \right\} \right] \right] \tag{20.20}
\]

After evaluating the integrals over the amplitudes, one obtains

\[
P(r_1 r_2 \ldots | DI) \propto \left\[ \prod_{l=1}^{m} P(r_l|I) \right\] \prod_{j=1}^{n} \left[ \frac{\gamma^2}{g_{j11} \cdots g_{j\nu\nu}} \right] |g_{jkl}|^{-\frac{1}{2}} \left( \frac{Q_j(r_1 r_2 \ldots)}{2} \right)^{\frac{N_j}{2}} \tag{20.21}
\]
with
\[ Q_j(r_1 r_2 \ldots) \equiv N_j \left( \sum_{i=1}^{N_j} d_{ji} - \sum_{\ell=1}^{\nu} \hat{A}_{j\ell} G_{j\ell}(t_i r_1 r_2 \ldots) \right)^2, \]  
(20.22)

\(|g_{jkl}|\) is the magnitude of the determinate of the \(g_{jkl}\) matrix defined in Eq. (20.18) and the amplitudes \(\hat{a}_{j\ell}\) are given by the solution to
\[ \sum_{k=1}^{\nu} g_{jkl} \hat{A}_{j\ell} = T_{j\ell} \]  
(20.23)

with the right-hand side of this equation given by:
\[ T_{j\ell} = \sum_{i=1}^{N_j} d_{ji}(t_i) G_{j\ell}(t_i). \]  
(20.24)

See [2], and [11] for more on how the integrals over the amplitudes are evaluated. Equation 20.21 is the joint posterior probability for the nonlinear parameters that is targeted by the Markov chain Monte Carlo simulations. These simulations only vary the nonlinear parameters, the amplitudes simply do not appear in the posterior probability. However, the amplitudes are output from the simulation. The output amplitudes are given by Eq. (20.23). Because these amplitudes are estimated for each value of the nonlinear parameters, there is as many samples from the distributions of the amplitudes as there is for each of the nonlinear parameters. Consequently, the model that use marginalization do output density functions for the amplitudes.

### 20.2 Outputs Form The Enter Ascii Model Package

The Text outputs files from the Enter Ascii Model packages consist of: “Bayes.prob.model,” “BayesModelAscii.mcmc.values,” “Bayes.params,” “Console.log,” “Bayes.accepted” and a “Bayes.Condensed.File.” These output files can be viewed using the Text Viewer or they can be viewed using File Viewer by navigating to the current working directory and then selecting the files. The format of the mcmc.values report is discussed in Appendix D and the other reports are discussed in Chapter ??.

Additionally, the “Plot Results Viewer” can be used to view the output probability density functions. In addition to the standard data, model and residual plots there are probability density functions for each parameter in the currently loaded Fortran/C model. These output probability density functions are named

\[ \text{ModelFileName.ParamName} \]

where \text{ModelFileName} is the name of the currently loaded model. For example, if you have a model named \text{MyFunnyExp} model, and it has a decay rate named \text{FunnyRate} the output file containing the posterior probability for \text{FunnyRate} would be named:

\[ \text{MyFunnyExp.FunnyRate}. \]

This naming convention also applies to derived parameters. So, if in addition to generating samples for \text{FunnyRate}, you also generated samples from a derived inverse decay rate, which was called \text{FunnyDecayTime} then there would also be an output file named

\[ \text{MyFunnyExp.FunnyDecayTime}. \]
MyFunnyExp.FunnyDecayTime

containing the posterior probability for the decay time. For more on writing Ascii models in either Fortran or C, see Appendix E.
